EXPERIMENT 10

PERFORMANCE OPTIMIZATION IN ZOHO CREATOR

AIM

To study and apply performance optimization techniques in Zoho Creator to improve application speed, responsiveness, and efficient use of resources.

DESCRIPTION

Introduction

Performance optimization means designing an application so that forms, reports, pages, workflows, and integrations respond efficiently. In Zoho Creator, performance depends on the amount of data processed, the complexity of Deluge scripts, report configuration, and the number of external services called.

Optimize forms and reports

Keep forms focused on the information users need. Avoid unnecessary fields and complex calculations. In reports, display only useful columns, apply suitable filters, and use criteria to reduce the number of records shown. Use appropriate search fields and avoid loading large amounts of data when only a small subset is required.

Improve Deluge scripts

Write simple, readable Deluge scripts. Avoid repeating the same fetch or calculation inside loops. Fetch records using specific criteria instead of retrieving every record. Store a result in a variable when it will be reused. Handle empty values and errors carefully so that a workflow does not fail unexpectedly.

Use workflows efficiently

Create workflows only for required events and avoid duplicate automation. Keep actions focused on the task. For long-running work, consider suitable scheduled or batch processing instead of performing every operation during a user's form submission. Test workflows after changes.

Manage integrations

External API calls can increase response time because the application waits for another service. Call only the endpoints required, handle unsuccessful responses, and avoid

unnecessary repeated requests. Check API limits and authentication requirements before deploying integrations.

Testing and monitoring

Test the application with realistic sample data and common user actions. Compare performance before and after changes. Review available execution logs and error messages to identify slow scripts or failures. Optimization should be based on observed behavior rather than assumptions.

Best practices

Use clear field names, reusable functions where suitable, precise record criteria, and consistent validation. Document important logic and retest the application after changing forms, reports, scripts, or integrations.

RESULT

The key performance optimization techniques for Zoho Creator were studied. Applying efficient reports, focused Deluge scripts, appropriate workflows, and careful API usage can improve application responsiveness and maintainability.
