EXPERIMENT 12

SECURITY AND GOVERNANCE IN ZOHO CREATOR

AIM

To understand the security controls and governance practices used to protect data and manage applications built with Zoho Creator.

DESCRIPTION

Introduction

Security protects application data from unauthorized access, alteration, or disclosure. Governance defines how applications are created, reviewed, maintained, and used in accordance with organizational rules.

User access and permissions

Give users only the access needed for their responsibilities. Configure roles, profiles, sharing settings, and record-level access where available. Review permissions regularly, especially when users change roles or leave an organization.

Data protection

Collect only the information required by the application. Protect sensitive information and follow applicable organizational policies and laws. Avoid placing personal data, passwords, access tokens, or confidential records in public reports or source code.

Authentication and integrations

Use approved authentication methods for API connections. Store and manage credentials securely using supported connection or secret-management features instead of hard-coding secrets in scripts. Review the permissions granted to each integration and revoke unused connections.

Validation and auditability

Validate user inputs and apply business rules consistently. Use available audit trails, logs, and change history to investigate unexpected activity. Keep a record of important configuration changes and test changes before releasing them.

Governance practices

Assign application owners, define development and approval responsibilities, document

data usage, and review applications periodically. Establish naming conventions, backup practices, retention rules, and a process for handling incidents.

Security checklist

Before release, verify user permissions, report sharing, form access, API credentials, validation rules, and logging settings. Test with accounts representing different user roles. Recheck access after every significant change.

RESULT

Security and governance practices for Zoho Creator were studied, including least-privilege access, data protection, secure API connections, validation, auditability, and periodic reviews.
